

Code Necessary for a JComboBox :

```
private JComboBox comboBox = new JComboBox();

comboBox.addItem( "Top" );
comboBox.addItem( "Center" );
comboBox.addItem( "Bottom" );
comboBox.setEditable( true );
comboBox.getEditor().addActionListener(      new
ActionListener()
{
    public void actionPerformed(ActionEvent e)
    {
        System.out.println("here" + comboBox.getSelectedIndex()
);
    }
}
);
```

This example uses a default constructor. You could also have used:

- public JComboBox(ComboBoxModel)
- public JComboBox(Object[])
- public JComboBox(Vector)

The most common way you will use a JComboBox is for making another object react to the choices expressed by the user. For this purpose, you implement the

ItemListener interface.

```
String[] numbers = { 'one', 'two', 'three', 'four' };
JComboBox cb = new JComboBox( numbers );
cb.setMaximumRowCount( 3 );
cb.addItemListener( new ItemListener()
{
    public void itemStateChanged( ItemEvent e )
    {
        someJLabel.setText( numbers[ cb.getSelectedIndex() ] );
    }
}
);
cb.getSelectedIndex()
```

This method returns an int, which becomes a subscript for the array,
