

```
public class Addition
{
    public static void main( String args[] )
    {
        System.exit( 0 );
    } // end of main()
} // end of class Addition
```

Add the main method, and `System.exit( 0 )`.

Next, we actually start with the program logic for the intended application.

```
import javax.swing.JOptionPane;
public class Addition
{
    public static void main( String args[] )
    {
        String firstNumber, secondNumber;
```

These two are “String” references. That means they have the potential to point to objects of type `String`. However, at this point they are empty references.

```
import javax.swing.JOptionPane;
public class Addition
{
    public static void main( String args[] )
    {
        String firstNumber, secondNumber;
        Int number1, number2, sum;
        System.exit( 0 );
    } // end of main()
} // end of class Addition
```

Now, we add three integer variables. They are not objects, and hold three integers (without any methods or classes). `number1`, `number2` and `number3` are called primitive variables.

```
import javax.swing.JOptionPane;
public class Addition
{
    public static void main( String args[] )
    {
        String firstNumber, secondNumber;
```
