

```
Int number1, number2, sum;  
firstNumber = JOptionPane.showInputDialog( "First Num"  
);  
secondNumber = JOptionPane.showInputDialog( "Second  
Num" );
```

Method `showInputDialog()` receives a `String` argument, and returns a `String` result. `JOptionPane` creates `InputDialog` boxes.

But, since the numbers are still `Strings`, we can't add them yet. We need some object that has a method capable of taking a `String` argument and returning an integer.

`JOptionPane` creates `InputDialog` boxes

```
import javax.swing.JOptionPane;  
public class Addition  
{  
    public static void main( String args[] )  
    {  
        String firstNumber, secondNumber;  
        Int number1, number2, sum;  
        firstNumber = JOptionPane.showInputDialog( "First Num"  
    );  
        secondNumber = JOptionPane.showInputDialog( "Second  
Num" );  
        number1 = Integer.parseInt( firstNumber );  
        number2 = Integer.parseInt( secondNumber );  
        sum = number1 + number2;
```

`Integer` is a class. Its method `parseInt()` takes a `String` argument and returns an `int`.

And finally, the code looks like:

```
import javax.swing.JOptionPane;  
public class Addition  
{
```
