

the APIs being put out as part of the HTML5 specification are in fact JavaScript APIs. Canvas, GeoLocation, IndexedDB, WebSockets, Web Workers and so forth are all JavaScript APIs, i.e., JavaScript is the primary mechanism by which you programmatically interface with these APIs. Today JavaScript and HTML5 essentially go hand in hand and the term “HTML5” is a bit of a misnomer because it is no longer just about markup!

How do we go about using it?

Using JavaScript in HTML5 web pages couldn't be simpler. JavaScript can be used in HTML documents in two ways:

Inline scripts

It is possible to interleave HTML markup with JavaScript. Here's an example:

```
• <!doctype html>
• <html>
• <head>
•   <title>JavaScript and HTML5</title>
• </head>
• <body>
•   <script>
•     document.write("Hello, world!");
•   </script>
• </body>
• </html>
```

The highlighted line is a simple line of JavaScript that uses the Document Object Model (DOM) interface to write a line of text to the document. You'll note that the “script” tag no longer requires a “type” or a “language” attribute to indicate that the language being used is JavaScript.

Include scripts

An alternative to embedding script inside HTML documents inline is to write them in separate files and then include them from the HTML file. An example follows:

```
• hello.htm
• <!doctype html>
• <html>
• <head>
•   <title>JavaScript and HTML5</title>
```
