

6. If you select the API version as 2.0, you also need to select the application type that you want to develop.
7. Click Generate.

Based on the name and version type information, the bada developer site generates a unique ID. The application ID is needed for basic configuration settings and application life-cycle management.

8. Click Continue.
9. Assign privilege groups, as needed, and click Finish.
10. Some of the bada APIs are so called privileged APIs that handle platform and user-sensitive data. To be able to use features and services provided by privileged APIs in your application, you must assign specific privilege groups to your application, based on the kind of application functionality that you want to develop.

After you have created the application profile and downloaded the manifest file, you're ready to create the application project.

Manifest file

All bada applications need to have a manifest file (manifest.xml). After creating the application profile, you can download the manifest file from the bada developer site to be used in your application project.

You don't need to create or edit the manifest file manually. The downloaded manifest file contains the relevant application information that you have defined in the application profile or that has been generated based on the profile, such as:

- ▶ Application ID
- ▶ Application type
- ▶ Assigned privilege groups
- ▶ API version

Creating the application project

After you've defined your application profile on the bada developer site and downloaded the manifest file, you are ready to create the application project in the bada IDE. The application project creation steps differ based on whether you are creating a C++, flash, or web application.

Creating a C++ application project

The following instructions are specific for creating the project with the bada Form Based Application template.
