

To create the C++ application project:

1. In the IDE, select **File > New > bada C++/Flash Application Project**.

If the project option you want is not visible, make sure that you are using the correct perspective (bada C++). To switch perspectives, go to **Window > Open Perspective > Other** and select the perspective you need.

2. In the New bada C++/Flash Application Project window, define the project details such as the name of your project, location for your application project or use the default location. Select the project type as bada Form Based Application, and click Next.

3. Select the Default manifest file check box to use the default device configuration, or browse for the location where you have stored the manifest file that you downloaded from the bada developer site, and click Next.

For the purpose of getting familiar with the IDE and SDK, you can also create an application without registering it on the bada developer site. In this case, you need to use the default manifest file provided by the SDK. An application that is developed using the default manifest file cannot connect to the bada Server and cannot be signed or sold in Samsung Apps Seller Office.

4. Make sure that the path for bada SDK root matches with the location where you have installed the SDK and that the Model for developing your application is correct, and click Next.

The SDK root path points to the latest installed SDK instance by default. Check that the name of the project is correct, and click Next.

You can also add vendor information and a project description.

5. Define a name and base class for the form, and click Next.
6. If you want your application to support target devices with different display resolutions, select the Auto-scaling check box, and click Next.
7. If you want other applications to have read and write access to the / Home/Share2 folder of your application, add their application IDs and click Next.

Defining trusted applications enables you to share your application files with other applications.

8. Your application can define whether notifications are displayed as tickers or full messages, and whether an alert sound and badge are used with notifications. Select the options you need from the Notification list.
9. If you want to export the functionality of another application for your application, specify the provider ID, operation ID, and AppControl category, and click Next.
