

CODING APPLICATIONS

Best practices while coding your bada applications...

When coding your application, you must consider the following issues:

1. Initialize the application resources using the `Osp::App::Application::OnAppInitializing()` (in the C++ framework) or `Osp.App.Application.onInitializing()` (in the Web framework) event handler.

Typically, the method implementation takes care of creating the UI and restoring the latest application states. Also, the `Osp::App::AppRegistry` class (in the C++ framework) allows the application to save and restore its data continuously.

2. Code application-specific features and functionalities, and handle events.

Remember to define how the application behaves during the application's state transitions, such as switching between foreground and background. The application must also define event handlers corresponding to system events, as necessary.

3. Destroy allocated resources and save the current application states using the `Osp::App::Application::OnAppTerminating()` (in the C++ framework) or `Osp.App.Application.onTerminating()` (in the Web framework) event handler.

The bada Web application can be developed in 2 different ways:

- ▶ Using the `Osp.Ui` namespace
