

was successful.

Packaging Applications with the Command Line

To build and package your application through the command line:

1. Run the following commands:

```
• cd <BADA_SDK_HOME>\Tools\MakePackage
MakePackage.exe TYPE_OPTION PROJECT_PATH
```

Where PROJECT_PATH is the location of the project to be packaged and TYPE_OPTION is the build configuration to be used:

- -td = Target-Debug
- -tr = Target-Release

For example, the `MakePackage.exe -tr C:\MyWorkspace\MyProject` command builds and packages the bada application project stored under `C:\MyWorkspace\MyProject` with the Target-Release configuration.

2. Check the package in the project folder to ensure that the packaging was successful.

Certifying and Publishing Applications

After you have packaged your application, you are ready to certify and publish your application.

To certify and publish your application:

1. Upload your application to Samsung Apps Seller Office for certifying.

Samsung Apps Seller Office compares the manifest file in the package to the original file that was created when the application was registered and defined on the bada developer site. Samsung Apps Seller Office checks whether the application functions properly.

If your application passes the check, it gets signed as a certified application installer package, `<Application_name>.oap`, which contains the `<Application_name>.zip` file and a `signature.xml` file.

2. Check your application to Samsung Apps Seller Office for selling.

Samsung Apps Seller Office checks whether the application functions properly. If the application is approved, the application status on the bada developer site changes from “Development” to “In operation”. When the application has this status, it is no longer possible for you to modify the application.

If the application is not approved by Samsung Apps Seller Office, its status remains as “Development”.
