

Create the form

1. The `Initialize()` method constructs the Form instance for the application (using the XML file created with UI Builder), and sets the first panel to be displayed.

```
• bool MainForm::Initialize(int panelId)
• {
•     Form::Construct(L"IDF _ MAINFORM");
•
•     if(panelId >= 0 && panelId <= 3)
•         __panelId = panelId;
•
•     return true;
• }
```

2. The `OnInitializing()` event handler is used to create instances and set styles for the form content. First, a header is created defining the title text for the form.

```
• result MainForm::OnInitializing(void)
• {
•     result r = E _ SUCCESS;
•
•     Rectangle clientRect = GetClientAreaBounds();
•     Rectangle rect(0, 0, clientRect.width, clientRect.
height);
•
•     // Create header
•     Header * pHeader = GetHeader();
•     if(pHeader)
•     {
•         pHeader->SetStyle(HEADER _ STYLE _ TITLE);
•         pHeader->SetTitleText("Basic App");
•     }
```

3. The a tab-style footer is created, and the footer tab items are defined. An event listener is added to the footer to allow the footer item clicks to be tracked.

```
• // Create footer
• Footer* pFooter = GetFooter();
• if(pFooter)
• {
```
