

NAMESPACE	PURPOSE
App	This namespace contains classes and interfaces that provide the basis of application development. It enables a web application to interact with the bada platform and other web applications.
Core	This namespace contains classes and interfaces for the building blocks of object-oriented programming. It provides several JavaScript APIs in addition to the set of standard DOM and EcmaScript APIs.
Locales	This namespace contains classes to make it easy to localize your application for international markets, ensuring that numbers, dates, and currencies are all displayed in a way that is appropriate for a particular location.
Ui	This namespace contains classes required for implementing a user interface (UI) for your application. The Ui namespace contains the base classes for all UI controls, as well as interfaces for event handlers.
WAC	This namespace provides access to native services available on the device, including calendar, camera, and accelerometer sensor.

structor, the instance members, and the static members. The web framework supports a closed form of the class declaration where the entire declaration is provided within the `define(name, config)` method. In this method, `name` is a fully-qualified class name, and `config` is a configuration map with various sections defined by keys:

```

• Osp.Class.define("My.Cool.Class",
• {
•     // Configuration map
• });

```

Class types

The web framework supports various class types, which are specified by the type key within the configuration map of the class definition:

▶ Regular class

Contains class variables or class methods (in the statics section), and instance variables or instance methods (in the members section).

A regular class can be instantiated using the `new` keyword:

```
var myClass = new My.Cool.Class;
```

Since the class can be instantiated with the `new` keyword, a constructor must be given in the `construct()` method.

▶ Static class

Is often a helper or utility class. A static class is not instantiated and only
