

- Touch
- Drag and drop

You must define listeners for controls to handle events.

Layout

The bada platform allows you to attach an `Osp.Ui.Layout` instance to a container. The position of a child control in the application UI is relative to the top-left corner of the parent container. However, attaching a layout to a parent container affects the size and position of all the child controls added to the parent container.

Layouts help you to organise controls inside a container in a sophisticated manner. Layouts are useful in handling multiple screen resolutions within the same application. They also help in positioning the controls without using absolute coordinates. With these features, you can design screens that look good in any device irrespective of the screen size or resolution. The `Osp.Ui.Controls.Form` class is a special container to which a separate layout can be added for the portrait and landscape mode.

The figure illustrates a screen designed using different layouts. The red lines indicate the vertical box layout components. Each component of the vertical box layout consists of a grid layout (indicated by blue lines) which in turn has other controls in it. The green lines indicate horizontal box layout components.

Using multiple layouts

Associating layouts with a container

Layouts can be associated with any container, though one layout instance
