

Framework

This layer contains C++ and web frameworks of bada. The C++ framework consists of the application framework, interfaces and classes that provide access to the functionality on the underlying layers. The application framework provides features for application life-cycle management, event handling, and application controls. The interfaces provided by the open API framework include several basic interfaces that are needed by all applications for handling data types, utilities, basic device features, and application states, and for creating the user interface. The web framework provides well-established standards and features, such as WAC 2.0, HTML5, CSS, and JavaScript, as well as JavaScript-based cross-platform APIs for UI controls and events.

Application model

The bada platform supports the following application types:

Base applications

These are stored in the ROM and cannot be removed using the Application Manager. Examples of base applications include dialer, contact, camera, and music player.

bada applications

You can install and remove bada applications from your device as per your convenience. These could be C++ or Flash applications created using the C++ framework, or a web application created with the web framework.

Users access bada applications through the device's main menu or task manager. The main menu displays the base and bada applications installed on the device, while the task manager displays the icons of the application history for both currently running and inadvertently terminated applications to provide the user quick access to them.

Multitasking in bada

The bada platform now supports multitasking with versions 2.0. However, when multiple bada applications are running simultaneously, only one application can run in the foreground, while the remaining applications continue to run in the background. However, the user can switch the application perspectives and determine which application runs in the foreground.
