

by the DestroyGL() method, dramatically improves the overall performance of the application.

1. The glDeleteProgram() method frees memory space and invalidates the name associated with the program object created in the InitGL() method.

```
void GlesCube::DestroyGL()
```

```
{
    if( __programObject)
    {
        glDeleteProgram( __programObject);
    }
}
```

2. The eglMakeCurrent() method is cleared to flush the existing EGL™ rendering context in the event that the new rendering context is the same as the existing rendering context. This helps in avoiding context duplication.

```
{
    if( __eglDisplay)
    {
        eglMakeCurrent( __eglDisplay, null, null, null);

        if( __eglContext)
        {
            eglDestroyContext( __eglDisplay, __eglContext);
            __eglContext = EGL_NO_CONTEXT;
        }

        if( __eglSurface)
        {
            eglDestroySurface( __eglDisplay, __eglSurface);
            __eglSurface = EGL_NO_SURFACE;
        }

        eglTerminate( __eglDisplay);
        __eglDisplay = EGL_NO_DISPLAY;
    }

    return;
}
```
