

hasn't matured enough to be considered one for major usage, and frankly, does not capture the attention of major developers the way its adversaries do. Hence, the only reason for hacking into your Belle device would be if you wanted to use some unapproved apps. This in turn, carries the usual threat of

warranty getting void, and of security issues/bricking. Nothing out of line here. Whether the deal is worth it, is entirely up to you.

6) PMP

Traditionally PMPs were devices that most manufacturers did not build with the threat of hacking in mind. After all, they used to be simple music/video playing devices – what more could you possibly get out of them! But then came the advent of iPods, and innovation after innovation led us to finally reach a stage where the proper PMPs of the day are basically smartphones minus the calling facility. And that is something that we actually cover – the possibility of making a call from a PMP over WiFi! While all these thoughts are fascinating, what must be considered here is that the support-stores network for PMPs is not as widespread as it is for other devices, and we again run the possibility of fighting the battle alone if a problem is encountered. Also, the main focus for a PMP manufacturer is that the rendering is as pleasing as it gets, and installing a different firmware to the one the device was built for, is bound to throw up some teething problems. The danger of bricking is very, very real in this regard.

7) Camera

With even low end cameras being built with sufficiently powerful processors and good image processing capabilities, its a shame really, that manufacturers are not providing the software capable to harness all of the possibilities here. And it is for this reason that firmware 'upgrades' like Magic
