

iFile

One thing missing from iOS is filesystem access. iOS intentionally tries to abstract away the file metaphor, which means that in many cases when you do want file access, you'd be left crippled.

iFile is a handy File Manager for iOS

iFile is an excellent file manager app (like explorer.exe in Windows or Finder on Mac) that gives you full control over your filesystem, letting you copy, move, and open almost all files residing on your device's storage. It also has a lightweight webserver built in, which lets you wirelessly transfer files from your PC or Mac via a web browser. The app is shareware, which means that a few features are not available in the free version. You can pay \$4 to buy or use the free version with restrictions.

F.lux

If you have ever used your iPhone in the middle of the night, in a dark room, you know how uncomfortable the bright light is to your eyes. F.lux, a name you might be familiar with from the desktop, adapts your iPhone's display by changing its colour as per the time of the day.

Activator

Activator is a tweak that gives you full control over the behaviour of hardware buttons and gestures throughout the OS. You can assign actions to various input methods like double tapping on the status bar, slide-in gesture from the edge of the screen, volume button press, mute button toggle, device shake and a lot more. The actions include showing music controls, locking the device, toggling settings, bringing up the Tweet dialog, or even simulate the press of any hardware button.

If your home button is unresponsive (a common problem with iPhones), you could define any button you don't use commonly, like the volume down button, to act as the home button. Another handy one is to tell Activator to bring up the multitask app switcher when you slide your finger up from the bottom of your phone's screen.
