

As for the technical details, this is what “Businesscat2000” had to say:

“The CPU isn’t emulated on Playbook (though it is on Windows). It works very similarly to how WINE works to run Windows applications on Linux. The app binary is mapped into memory and imports are resolved to point to my own implementation of the various APIs needed. iOS actually uses a few open APIs already, which Playbook supports just as well ([Open] GL ES, and OpenAL). The bulk of the work has been in implementing all of the objective C classes that are required. The ARM code of the applications run as-is - the armv6/v7 support on PB/iDevices are pretty much identical, and the code is designed to run in USR mode. No SWIs, GPIO accesses or any of that kind of shenanigans.”

He posted a video of iOS apps like Super Monkey Ball, Tiny Tower, Sushi Cat, Galcon, iFart and a few others running on his PlayBook.

Since the task of getting iOS apps to run on a PlayBook is really hard to believe, other users questioned the legitimacy of the software and raised doubts. But after running a variety of iOS apps, including some that were exclusive to the platform, people were finally convinced.

Although the icons don’t show up on the PlayBook homescreen, the emulation software is capable of loading up to 10 iOS apps at once. Also the apps have a resolution of only 480-by-360-pixels. Presently “Businesscat2000” says that the software isn’t fit for public consumption, and would only be released after it is polished enough.
