

▶ **Nokia QWERTY keyboard editor**

This nifty tool allows you to edit the qwerty keyboard on S^1, S^3 symbian devices.

▶ **Theme Icon switcher**

You can use this to switch icons in your themes to suit your needs. Or one can open the theme in Carbine.ui and edit it there.

▶ **RSC Editor**

Allows you to edit the .rsc file which stores all the visible text in the program. Quite useful if you wish to translate a program or add a new language in an application altogether.

▶ **PPMod**

One can modify core files of S40 firmware (.ppm files) using this software.

HACKS

Installing Unsigned applications

Often we come across errors regarding application certificates being invalid and subsequently applications cannot be installed onto your symbian device. There are a couple of workarounds for this, some involve hacking your phone and then again one could take the easy way out by getting those applications signed using your own custom certificate. We'll go through both methods.

Get a Custom Certificate

This method involves getting your own developer certificate which when used to sign an application will grant it all rights on your phone and you'll be able to utilise all features of that phone. More and more developers now provide unsigned applications and using your own certificate goes a long way in reducing restrictions as they are bound to the IMEI (International Mobile Equipment Identity). Here is how you can obtain Dev 17 certificate (17 capabilities developer certificate) for your phone.

1. Goto <http://www.s60certkey.com> and register an account.
2. Once done you'll be able to obtain three S60 certificates for free. For more certificates one can make a new account or get in touch with the site admin who'll grant more requests for a small donation.
3. Enter the IMEI number of the S60v3 or S60v5 device on which the applications are to be installed. The IMEI number can be easily obtained
