

the screenshot above. They are self-explanatory in terms of the functions they perform. Like the 'saveclipboardafterreboot' patch saves stuff you copied even after you reboot your phone and 'savelogsafterchangingsim' saves your call logs even after change of sim card. You can find more of them on the internet.

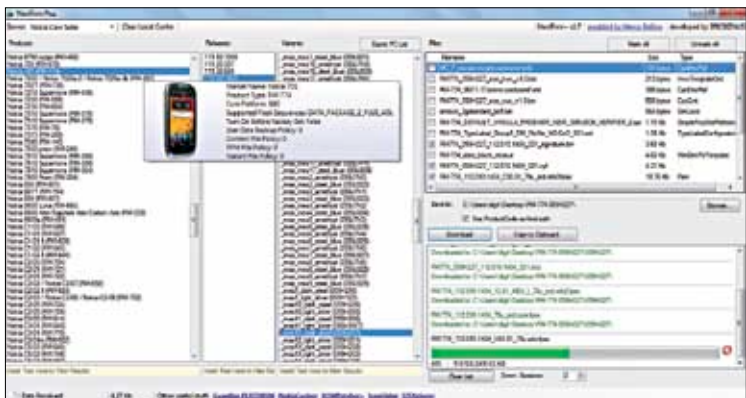

Cross Flashing

Sometimes all you need to do to enable new features is to flash the device with the firmware of a similar model. Now, the word 'similar' in this context means they must have the same hardware, only minor differences are allowed. Example - The 6300b which is the North American version using the 850/1800/1900 MHz band whereas the 6300 uses the 900/1800/1900. These locked phones can be used in other countries after cross flashing the 6300b phone with a 6300 firmware. This only unlocks the 1800/1900 bands as the 850-900 band is actually limited via hardware, so for a full conversion you'll need to modify the hardware a bit too.

Sometimes firmwares are region specific and newer firmwares are released in only select regions, so you can flash your phone with those firmware but that isn't cross-flashing in its true definition. Just ensure the RM-xxx number is the same to avoid any issues.

Flashing your Symbian Device using Phoenix

As we already mentioned, flashing is basically replacing your firmware files with modded ones.

Download the firmware for your device using Navifirm
