

# HACK YOUR CAMERAS

A camera, whether it's a Point And Shoot or dSLR, is able to take pictures thanks to the combination of hardware and software bundled into the system. When we talk of hardware on a camera it can include a whole bunch of things. The body, the lens, the sensor, the battery and many other things constitute the hardware side. The software part of this system relates to the code that enables you to fiddle around with settings such as exposure, whitebalance, aperture size etc. Right from the user interface to the algorithms that process the image that the sensor captures is the software. This software layer is not technically an operating system but it does communicate with the underlying hardware. In the case of cameras and other embedded systems its called the Firmware and enables the user to interact with the hardware modules of the camera.

Often changing this firmware can greatly enhance the feature-set of the camera. How is that possible? There are a couple of reasons. Camera
