

able or worthy addition to desktop / laptop computers; so in this context it is important to also note that this is something people still say about the mouse. Before GUIs computers were mainly used in solving mathematical problems and processing textual information. For people still using their computer for those tasks the addition of a mouse probably led to no increase in productivity.

However with GUIs computers have become increasingly capable of being used for manipulating images, videos, audio, 3D scenes and much more, all of which involve some form of spatial manipulation, and are best done with a mouse. Once touch and multitouch becomes even more ubiquitous, we will find ourselves with a whole range of uses for a computer that would traditionally have required significant manipulation with a keyboard and mouse.

Code editing tools gain little from the addition of a mouse

keyboard and mouse in addition to a touchscreen. While a purely touch-based device is not more productive than a traditional keyboard-mouse-based device, the addition of touch to an existing keyboard-mouse setup can certainly improve productivity. After all it is adding a whole new way you can interact with your computer.

Even today, software developers or writers can get a lot of work done without having to touch the mouse at all. When you do use the mouse though, it is in a situation where it will lead to the desired result quicker. Over time as one uses a computer, they develop a sense for using the right tool for the job; and touch is just another such tool. Future app developers that

One of the most famous criticisms of touch screens for desktops is the 'gorilla arm'. Imagine using a 24 - inch touch screen for many hours a day. Keeping your hand extended towards a screen for hours is just not feasible. There is some merit to this, but the thing most people forget is that when you talk of touch screens on a desktop, you are already talking about a fixed device that is very flexible, there is no good reason for it not to have a
