

Likewise you can have the messenger app or a social networking app open alongside another application. The application needs to support this view, and generally they do, but there is no guarantee that the application will be very useful in that mode, some apps do this better than others.

To snap fit apps, you can drag an app from the Modern UI task manager and move it towards the left or right side of the screen, Windows will indicate that it can snap the application there, at which point you can drop it. If you drag an app from the task bar to the centre of the screen it will just replace the currently running app rather than run alongside it. If you drag an app from the task bar to the bottom of the screen, that will just close the app.

A slider will also appear between two apps open side by side. This slider can't be arbitrarily moved either, but can be used to change which app is the primary and which is docked.

These gestures can be performed using the mouse as well, using the mouse you can even drag and drop a running app from its top edge to left / right side of the screen to dock it, or to the bottom to close it.

These operations also be performed using the keyboard. You can find those later in this booklet.

The Lock Screen

When you start your computer, before you see the login screen, you will see the Lock screen. There is not much to do here other than to get rid of it, but it does show some important information from your running applications.
