

How to enable Hyper-V

mac without requiring virtualization software, performance doesn't have to degrade. VHDs can be used to quickly deploy Windows images (installation images) onto multiple PCs, can be booted via USB drive and help carry the entire office setup to your home as well. You can have more than one VHD installation with different applications installed in each – allowing multiple installations

for different kind of users without having to mess up the entire partition table. And in case you want to remove the OS, just delete the VHD, remove its entry from the boot menu and you're done. Beware though – it's not all sweet. It has its downsides – about 3-5% drop in performance (not that it's noticeable enough), no hibernation, no BitLocker support on the host drive etc. Also, you have to add a boot menu entry if you want to boot via a VHD – Windows doesn't automatically do that for you.

Active Directory

No, this is not really a directory. It's a service available in Windows Server Editions. Active Directory Services (or ADS) empowers an organization to take control of its office computers. ADS is used to create "logical domains" of computers and enforce security rules throughout the domain at different levels of granularity.

ADS can be used as a central password storage tool – when a user logs in to the domain on a client computer, the domain controller (the computer running the ADS) checks for the password and determines the type of user

that has logged into the client computer. It would then initiate the login process for the client and send the list of security policies which the client must follow. Policies of different types can be implemented via ADS. Controlling
