

With growth and advancements in the field of electronics, wireless communications, networking, cognitive and affective computing and robotics, devices around you communicate in more ways than you ever imagined. Those times are not very distant when every object around us will have a small processor/sensor embedded within itself, invisible to us but still

communicating with all other devices around, making our lives more connected and accessible than ever before.

The future of embedded systems lies in the advancement of technologies that enable faster communications, heavy data storage capacities and highly interwoven connections among the devices. Before diving into the enormous number of applications of embedded systems, let's discuss the seven buzzwords that will define the future of embedded systems.

The future of embedded systems

Ubiquitous computing

Ubiquitous Computing is a branch of computing that focuses on interconnected and communicating devices carefully integrated into the objects we interact with in our daily lives. These objects can be anything right from your clothes to your toasters and coffee mugs. Smartphones and tablets are currently the obvious targets for applications aiming at ubiquitous computing, but in the future, don't be surprised if your game console talks to your smartphone's calendar about how "busy" you are today. The term Ubiquitous Computing (Ubicomp), also known as Pervasive Computing, was coined around 1988 by Mark Weiser when he was heading the Xerox Palo Alto Research Center (PARC). Sentient Computing is another form of ubiquitous computing which involves using various kinds of sensors to sense the environment and react accordingly. All over the world, research
