

```

• log(tab.url.replace(/\\/g, '\\'));
• if(tab.url.replace(/\\/g, '\\') == tabInfo[0]) {
•   a = tab.title + ", " + tabInfo[1];
•   break;
• }
• else
•   a = null;
• }
• log("a :" + a);
• return a;
• }
•
• </code>

```

It's important to note that the data given out by the multi-reporters is structurally different from what we'd expect, with the URLs consisting of backward slashes rather than forward, among other things. Now, in computers, backward slashes are generally used to escape the following character or to perform a special function. But we obviously don't want that to be happening with our data, so we proceed to fix the situation by some minor string processing to bring this data in line with our expectations, and much closer to what we'd have pulled from the single reporters. Also, the end-user would probably not be very interested in the URL of the tabs in our page, but rather the page title. Therefore, we replace the instances of URL with the tab title wherever we can. This attempt would fail if we were dealing with some internal Firefox page instances that we don't necessarily see in the interface as a user.

```

• <code>
•
• function oneReport(aProcess, aUnsafePath, aKind, aUnits,
aAmount, aDescription) {
•   // This function will be called once for each entry
from the
•   // multi-reporters. aUnsafePath has the full name,
and
•   // if aUnits == 0 it means the amount is in bytes.
(this is the only
•   // one that is relevant for us)
•
•   if (aUnits != 0) {

```
