

ible for larger screens with its offering in the tablet category – iPad. The OS was redesigned for the tablet which meant that it was able to adapt to the higher resolution and bigger screens of the iPad and carry out a seamless transition. There were some changes made in the UI to allow it to be perfectly suitable for a large screen. Some of the apps also received tweaks to handle this transition. iOS 3.2, which was the iPad compatible OS also began Apple's journey to a design feature that become a staple in Apple's System designs. It is known that Steve Jobs was a fan of the concept of skeumorphism which is essentially a design principle that incorporates a sense of realism to elements on screen. So a phone book will look like an actual phone book and the save button looks like a floppy drive because historically data was saved on one of those. While skeumorphism has its place and is quite an effective design concept, it was not loved universally. Apple retained this design feature in its future releases and it took quite an initiative from the design to team to finally kill it in the latest build – iOS 7.

iOS 4 finally introduced the key element that denied iOS the title of a true

performer – multitasking. This was the headline feature introduced in the iOS 4 and it granted the iPhone system protection from memory grabbing applications that run in the background. Though it differed from the traditional definition of multitasking and did not allow user to run apps in the background even if they wanted to, Apple did build some neat multitasking features that were good enough to satisfy the ever increasing market for the iPhone. Along with multitasking abilities iOS 4 had some great new features like face time, spell check and app folder creation. Support was added for the high resolution retina display along with some email customisation options. iOS 4 ensured that Apple stood stiff in the competition with Android. Apple also introduced upgrades to iOS 4 to rectify the “fake” signal strength
