

of that keyboard and not every developer does so. There are times when you'll come across as many as three different keyboards depending on the app you're using. Again, this is a minor issue but something that is vaguely irritating given the care that's taken everywhere else.

Another keyboard

Mail

Apple introduced (finally) the concept of background updates for apps. It's a feature that iOS users have been clamouring for and when Apple finally delivered, they did their usual one-step forward, one-step back routine. Now, if you're using the Mail app, you'll get a notification the instant the message is loaded as opposed to when your device gets a notification that it has received the mail. The problem is that sometimes it can take a few minutes for the mail to download fully and you won't be aware you received any mail till that download is complete. Why you can't get a notification instantly we don't understand. The app should ideally give you the notification and then update the mail regardless of whether you open the app then and there.

Mail alerts aren't quick enough

The bigger picture

What we're really trying to say is that there's nothing too far wrong with iOS 7, on the contrary, it's the most functional version of iOS yet. The problems are all minor, mostly design related and definitely lack the spit and polish that we expect from an Apple device. As it stands, iOS7 seems more like an OS that has been slapped together as quickly as humanly possible and there is a lot of room for improvement. These minor issues stand out so much only because we've come to expect that Apple will release a product that is polished and well-made and flaws, however minor, are jarring.
