

- **UIAttachmentBehavior** : This object lets you create a connection between two dynamic items that can move simultaneously. You can also tweak the oscillation and damping variable to fine-tune the movement.
- **UICollisionBehavior** : This object handles collisions of dynamic objects.
- **UIGravityBehavior** : This object allows you to define a gravity vector for its objects for dynamic objects.
- **UIPushBehavior** : This object defines a force vector for your dynamic items.
- **UISnapBehavior**: This allows you to snap an object with a pre-defined behavior.

Once you choose the behavior you want, you need to add that behavior to an animator object, an instance of **UIDynamicAnimator** Class. This animator object can be given multiple dynamic behaviors as per the developers need.

Also, iOS 7 introduced a new text kit that allows fine typography and better handling of text using columns, paragraphs and multiple font styles. You can now edit, show, stylize and store text without writing many lines of code. **NSAttributedString** class is tweaked to handle new attributes. You can define the region in which a text is laid out by using **NSTextContainer** Class, while **NSLayoutManager** helps you in generating glyphs and text layouting.

Multi-tasking

With iOS 7, you have access to new multi-tasking features that let you push app data in the background thread and apps can be set to awake at certain regular durations periodically to fetch details/data. The new APIs intelligently schedule updates and allows content updates only when the device is connected to Wi-Fi or a good 3G connection. As developers, you get the opportunity to push notifications about a new content update if you want.

The 3 new APIs include:

- Background Fetch
- Remote Notifications
- Background Transfer Service

Background Fetch

Imagine you are creating a web-feed app that needs to be updated with content from the web periodically and the user needs to be shown updated content

Multi-tasking on iOS 7 with push notifications
