

as a developer to allow hardware controllers for your app. You can configure hardware controller for your app and if the hardware is connected wirelessly or physically to the users iOS device, you can take controller inputs. The only guideline that Apple provides is that your game should be playable without the controllers also, thus making controllers optional.

The Sprite Kit and how it works

Multi-peer Connectivity and Airdrop

iOS 7 comes with ability to allow multi-peer connectivity meaning devices nearby each other can be connected and can communicate without the need of internet connectivity. Developers can use this framework to share data and services among nearby devices seamlessly. Using Airdrop, your apps can share docs, pictures etc with multiple devices that are nearby. You need to add an activity sheet and peer-to-peer sharing is taken care by Airdrop without requiring any complex network config.

Maps

As a developer, you can now take advantage of Apple Maps by integrating them into your apps for navigation. Apple maps have significantly improved since the last release and have an added night mode that automatically turns on once the sun sets. As a developer, you get access to direction API using which you can enable your users to get directions to their destination. You also have greater control on the overlays by having the ability to stack layers in desired manner and ability to replace parts of a map if needed.

64-bit Support

With iOS 7, you can compile your apps for 64-bit run-time. All the frameworks support both 32-bit and 64-bit run-time and your apps may run faster with 64-bit run-time as it has extra resources available.

JavascriptCore Framework

iOS developers generally don't use javascript much, and until iOS 7 there were limited ways in which an iOS app could interact with Javascript. With newly
