

such a thing as too much of a good thing.

2014 finally is the most promising. Not only will several landmark patents expire this year, it also marks the year when the 3D printing processes rewrote yet another age old industry. The person in question behind this revolution is Professor

Cody Wilson's Liberator

Behrokh Khoshnevis from the University of Southern California. With the help of a super sized 3D printer that spits out concrete, Professor Khoshnevis and his team managed to build a 2,500 square foot house in 24 hours.

The process is called contour crafting and it involves the laying down of two rails on either side of the site. The contour crafting system would move back and forth on these rails and lay concrete layer by layer. The design would make provisions for wiring and plumbing which would be assembled by hand along with the doors and windows.

While at the surface this technology makes that unaffordable dream home of yours a little more tangible, Contour Crafting has the potential to make construction sites safer and could prove to be of great use in disaster relief measures, with the potential of getting entire countries back on its feet.

Khoshnevis claims that his invention won't take away jobs but in fact create more and contour crafting is being considered to be a feasible means of colonising the moon. Hmmm...

Dream home anyone?

If we were to say 3D printing has come a long way, we'd be really underplaying the way the future is shaping up to be. Let's now turn towards the future of 3D printing.

As it is with all technology, with time and research would come a drop in costs. What this
