

Spoil your kids with a new lunch box every day

unless you are deep in to medical transplants and aerospace engineering, you should stick to the FDMs and the SLAs.

Additional Bonus: What to expect in the near future **Biodegradable Lunchboxes**

One really awesome thing we can expect is the gradual weaning away from petroleum based plastics. The good news is that our eco-friendly

plastic- PLA is now food grade! Scientists at Taiwan's Industrial Technology Research Institute have developed a type of PLA that doesn't become a pile of mush when heated and can be used to serve food. What they have done to achieve this is that they have developed a non-toxic nucleating agent that accelerates the crystallization rate of PLA. Why this is important is because PLA is derived from grains and sugarcane and is supremely green. The icing on this 3D printed cake is the fact that it is possible to derive this type of PLA from lactic acid too!

Where can I find more?

The entire RepRap community and all future developments in their models are available at reprap.org. You can find detailed videos explaining how to construct and troubleshoot your RepRap Prusa Mendel.

Are there any alternates I can consider?

You could take look at the Eventorbot by RepRap or the Prusa Mendel i3. Both have a better finish with all the wires and motors hidden away but are slightly more complicated to construct.

Printbot makes a bunch of kits that only require assembly and are not that bad on the wallet but one also needs to factor in shipping costs and like I mentioned before the OneUp and TwoUp 3D printers are also really good alternatives but they comes fully assembled so the fun of building your own 3D printer is lost.

I don't think I will be able to do this!

If these are the words running through your mind then slap yourself and let these awesome people who have done it before inspire you.
