

The template library available with most CAD programs make the task of designing original objects exponentially easier than the past generation.

aspects. Users can use the what-you-see-is-what-you-get approach to alter this design using input devices like a mouse. By adapting and tweaking these basic shapes together in pre-visualised methods, users are able to create unique designs and start their design work.

The other category of design software that is used is known as “surface modeling” and was originally used in the animation and entertainment industry. The software’s key ability lies in being able to virtually replicate and automate the surfaces of three dimensional models. We see this being applied in 3D animated movies and games, where character and environment surfaces have a great degree of detail, accuracy and authenticity, bringing them closer to the real world.

Solid Modeling CAD

Solid modeling CAD programs have been in use for industrial design and manufacturing for decades. They are able to render complex geometrical shapes that are customisable for designers to experiment and create. For example, using a solid modeling CAD program a designer can use basic shapes like adding together two cylinders to make a hammer and then subtracting a third cylinder to create a hole on the “handle” part of the design. Keeping in mind this already developed system and language of design, most 3D printers are created with the ability to accept these design file formats.
