

Geotagging

This feature takes advantage of the GPS on your phone to locate your position on the planet and then save the location coordinates into the EXIF data of your photos. Later on, applications that can read geotags will let you see your photos on a map so you can see exactly where you took a particular photo, in case you have a particularly bad memory.

If you don't want other people seeing your location information when you share your images, it is recommended you disable geotagging from your camera settings.

HDR

HDR stands for high dynamic range imaging. Scene modes are like presets

To understand what HDR is, we must first understand what dynamic range is. The dynamic range of a camera determines how much detail it can resolve in the light and dark areas of a scene simultaneously. A good camera will have a wide dynamic range, which means it will be able to resolve details in the bright and dark areas simultaneously. A camera with poor dynamic range will tend to blow out bright areas to pure white spots with no detail and dark areas will just appear black.

It's not always possible to have a camera with exceptional dynamic range every time, especially in mobile phones. Even when you do have a very good camera, it is not always possible to capture all the detail in a scene, especially with those with extreme lighting conditions. This is where HDR comes in.
