

world becomes feasible and is only becoming easier by the day. The number of mobile users in America has already exceeded the number of PC users, and it's only a matter of time before the whole world follows this trend. This only means that the average student is equipped with more powerful technology than ever before, which in turn only points to a plethora of apps coming out that take advantage of this and make way for new e-learning trends every day.

So what does the future for e-learning look like? Well, there is no limit for the dreamer really. Let us remind you the famous scene from 'The Matrix' where our protagonist Neo lies down in a fancy chair and straps himself onto a bunch of electrodes and just downloads a series of martial arts training programs into his brain, opens his eyes and all of a sudden, knows kung fu. While this might seem ridiculous, this might actually be the future that we're heading towards. fMRI (functional Magnetic Resonance Imaging) is a functional neuro-imaging procedure that measures brain activity by detecting associated changes in blood flow. So for any activity that involves visual performance

E-learning might make text books moot in the future

(such as catching a ball), all you need to do is find a person who's really good at that activity, put him/her in the machine, and then records the patterns in their brain while they visualise performing that activity. All you need to do is put yourself into that fMRI machine, and using neuro feedback, induce the brain patterns of the earlier person into yours. Your brain thus
