

LOOKOUT FOR YOUR LINUX

Let's not forget Tux shall we? In this chapter we show you how to backup your linux system

You don't need us to tell you how important backups are - you probably (and should) know that already. In an age where we're living such a great percentage of our lives digitally - through our digital photos, digital music library and digital documents, it's imperative that you have a way of recovering your data should something happen to it. In spite of it, taking the time to set up a foolproof and automated backup system is something we'd rather put off until disaster strikes - when it's too late to do anything.

Configuring backups doesn't have to be an exercise in tech wizardry, and most backup tools, even on Linux, are of the simple set-it and forget-it type. Meaning, you configure the files you want backed up, the backup location and the backup frequency, and let the program take care of the rest. The backup utility will run in the background silently, without your intervention, and if set-up properly, restoring data from your backups should be a breeze. Having said that, you should practice restoring data from your backups at least once, as backups are next to useless if you don't have a way to safely and quickly restore your data and resume work.
