

shows the audio levels of the final edit. Its a small but critical section as it tells you the objective audio volume quality of the final edit.

The Program Monitor Panel is where the whole of the Time Line is running. Although both the Source Monitor and Program Monitor playback the footage, only the latter shows you the entire run through that is present in the Timeline including all the edits and effects have been selected. The Program Monitor also contains a series of options at its base similar to a video playback software but with greater detail. Below the Program Monitor is a wider sub-window that is called the Timeline and this is where the “edit” process takes place. Users select their clips in the Media Browser, trim them in the Source Monitor and place them in the Timeline so it can be juxtaposed with other clips and moved around in a non-linear order to see what looks good to the editor.

The Timeline initially looks blank but once a project begins starts of with a tabbed active panel called a Sequence which shows a series of etches at the top of the panel with

time codes marked off. Depending on the Timeline and Project options, the Timeline can can a single field or multiple sub-sectioned timelines where overlapping video clips can be placed. Each video clip is paired with its audio clip the former above the latter. By default these two formats - video and audio - are linked as they originally were when recorded, but can be delinked and individually manipulated. Video clips can be organised in any order, effects can be imported from the Effects Panel to the Clips here and a single seamless view can be seen of the whole project.

The Tools that are used to make most of the editing changes are fairly intuitive and common sensical transposed from manual editing techniques. They can usually be found near the Timeline. The basic tools like Selection Tool and Blade Tool or the Razor Tool are used most often. The former is used to select the desired clip and the latter can be positioned across any part of the clip to “cut” it. The Blade tool fragments the desired clip at any position and can be used to extract smaller parts, even as small as a single

From a single laptop to a customised console configuration, editors use many different tools to do the same job.
