

sound and make your lies a little more believable. No, we're just kidding. Nobody will believe your message when your sound is dubbed in studio.

Stu-stu-studio!

Now that you've recorded all your samples, it's time to bring it to the studio and work that studio magic.

Obviously you will once again need a few things before you begin. For starters, a computer and a DAW or Digital Audio Workstation software. This is that actual business end of any studio, but isn't the most important. These software include names like Avid's Pro Tools, Steinberg's Nuendo, Sony's Vegas and a whole bunch of others, each claiming to be number one. It would always make sense to go in the direction that has the most number of plug-ins available.

Stu-stu-studio

A plug-in is an addition to the software you're using and serves the purpose of enhancing the audio. It could involve reverbs or echos, delays, chorus effects, noise cutters and a whole bunch of things that make life so much easier and make the sound pop a lot more.

Attached to the computer, a sound card. While the sound card that comes with your computer might be pretty ok, the real problem comes in when you're going to fire up a DAW software and expect your computer's processor to handle both tasks of running the software and processing the sound that's being played back.

Virtually every other issue you will face is directly correlated to how big a production you're working on. If you're working on an album, your built-in sound card won't cut it because it's just not high quality.

When you move sound through wires, it acquires noise. Noise is everything that makes sure your sound isn't clear. A good quality sound card, typically the ones that aren't inside your computer, is made of high quality materials that ensure that the noise added to the sound is kept to a minimum.
