

export the entire session as a FLAC or a WAV and import them once again. The first method is pretty handy when it comes to making stereo recordings. Unless you have a stereo mic, all mics are mono and will record only on a single track. So to make a stereo track, all you have to do is select the track and duplicate it

Part A and B

by hitting Edit and then 'Duplicate' (Ctrl + D). When you mix and render these tracks, you will have a proper stereo track.

The Generate option right next to it can be used as a rudimentary drum machine and you can create mixes and loops by playing with the time, the pitch and the frequency.

Once you are done with your mix, it's time to export your project. Hit File and then Export (Ctrl + E) and you get a dialogue box. Here you can choose where to save, what to name it and what format it needs to be.

Composing Without Instruments

If you don't own any instruments and you're trying to compose tracks, then your only option is to mix a whole bunch of loops and samples together.

Loops, as the name suggests are sounds that can be repeated multiple times. It's sort of how acapella bands do their stuff. Sampling is done by recording sound by a digital recording device. Now that you have a digital copy of that sound, you can use your sampling software and play it back at varying speeds, altered pitches and string them together to make loops.

You can find a lot of royalty free loops and samples at flashkit.com/loops, sampleswap.org and freesound.org.

Now that you've acquired the raw materials, let's brew some music.

While these samples and loops can be brought in to Logic and a few other commercial software, the best option on the open source front is LinuxSampler. But because installing it is kinda complicated, the alternative to it is LMMS or Linux MultiMedia Sampler.
