

Jumanji surprises again

Jumanji has been doing really well in the box office, so much so that it has surpassed Spider-man: Homecoming in the domestic box office (US). <http://digit.in/jmniSpdrmn>

Black Panther's family tree

Marvel has released Black Panther's family tree in a rather detailed video. <http://digit.in/BPfam>

We all know about the hardy water bears, but we are surrounded by other microanimals with superpowers of their own.

Dust mites are arachnids that live in human homes, and feed on human skin flakes. An average adult human sheds enough to feed one million dust mites every day.

Copepods could form the largest animal biomass on the planet. They are small crustaceans, and mostly do not have hearts. They absorb oxygen directly from the surrounding water.

Cladocera, also known as water fleas have antenna sensitive enough to identify locations of hiding prey. They are born with two eyes that later fuses into one.

Spider mites are tiny arachnids mostly eat plants, and weave webs to protect themselves. The live on the under-sides of leaves. They can damage crops, which is why they are considered pests. They can reproduce so rapidly that they evolve and adapt to most pest control measures.

Loriferans are multicellular animals that occupy as much space as a unicellular organism. They have brains, a digestive system, muscles and sense organs, but no circulatory system. They are the first known multicellular organisms to survive in an oxygen-free environment.

Thousands of nematodes can be found in a handful of soil. When faced with harsh conditions, Nematodes can go into cryptobiosis, freezing all life functions till the conditions are favourable.

Rotifers can go into cryptobiosis like the nematodes and tardigrades. Some species produce degenerated males that cannot even feed themselves, they just fertilise the eggs and die.
