Google removed the "view image" button in Google Image search post a lawsuit by Getty. Getty have since dropped the lawsuit. <http://dgit.in/whereimage>

Dyson electric cars?

Popular vacuum cleaner company Dyson is looking to venture in electric cars, and possibly, solid-state battery tech. <http://dgit.in/dysoncars>

ISRO has launched a number of satellites that tested deorbiting strategies

ISRO has launched a number of satellites on its workhorse rocket, the PSLV, that were attempts to demonstrate various deorbital strategies.

CNUSAIL 1

Launched by the PSLV-C40 mission, along with 30 other satellites, the satellite is an attempt to test the viability of a drag sail to deorbit

a satellite. The sail works by interacting with the particles in the upper atmosphere. As a passive deorbiting measure, drag sails have the potential to be used on nanosatellites and microsatellites, which have limited space available for fuel and active propulsion systems. The satellite was built by students of the Chungnam National University in Korea.

mission successfully demonstrated the viability of a dragsail to deorbit a nanosatellite. The sail was folded up and is designed to fit in a standard 3 unit of the CubeSat standard, a platform for nanosatellites.

URSA MAIOR

The URSA MAIOR satellite launched on the PSLV-C38 mission, measured the electron density in space. At the end of the mission, it has a dragsail payload as well, to safely deorbit the satellite. The dragsail is developed by Space Mind and is called ARTICA,

product is the D3 decommissioning device, which uses active propulsion to deorbit satellites in various orbits. The onboard propulsive device on the D-Sat fired successfully, but a direct and controlled decommissioning was not achieved.

NLS-19

Launched on the PSLV-C35, the NLS-19 is also known as the CanX-7 and was built by the University of Toronto Institute for Aerospace Studies in Canada. The satellite successfully demonstrated four drag sails to deorbit a nanosatellite, with each sail measuring about one square metre. The modular drag sail actually

fits on the outside of a CubeSat, so there is ample space on the interiors for the primary payloads.

INFLATESAIL

The PSLV-C38 mission had thirty one passengers on board, out of which three were technology demonstration satellites for deorbiting technologies. The Inflatesail project was handled by the Surrey Space Centre, which has announced that the

onstration satellites for deorbiting technologies. The Inflatesail project was handled by the Surrey Space Centre, which has announced that the

short for Aerodynamic Reentry Technology In CubeSat Application. The sail occupies a standard 1 unit on a CubeSat, and is designed to be a cost effective, modular deorbiting solution.

D-SAT

Also launched on the PSLV-C38 mission, the D-Sat was built by a company that specialises in creating technologies for deorbiting satellites, and is called D-Orbit. Their main

because of advances in miniaturisation and fuel technologies.

ELECTRODYNAMIC TETHER

The Kounotori 6 satellite launched by JAXA last year was an effort to test a deorbital strategy that allows a satel-

lite to capture debris with an electrodynamic tether. Unfortunately, there were problems with the deployment of the tether. Tethers unlimited is also developing solutions for deorbiting satellites, including a Terminator Tape for low altitudes and a Termina-

tor Tether for higher altitudes. The Terminator Tape uses the energy collected by moving through the Earth's magnetic field to induce a passive drag force on the satellite, which will eventually slow it down enough to do a re-entry, which would burn it up.
