

The Boom plane in development is designed to make available affordable supersonic travel for everyone.

AIR TRAVEL IS NOT GETTING FASTER

Airplanes offer just about the fastest way to travel, but current planes travel at speeds that are lower than the planes in the 60s and 70s. With the advancement of technology, one would expect planes to keep getting faster, but that is not really happening. Passenger aircraft today cruise at top speeds of about 900 kmph, and bullet trains in Japan travel at about 600 kmph. Hyperloop promises to ferry passengers at speeds exceeding that of planes. Here is why air travel is not getting any faster.

You are always flying Economy, even when you pay for First Class!

Modern passenger aircraft mostly use turbofan engines. Turbofan engines channel air through two routes, an internal combustion chamber next to a high pressure turbine, and another channel around the turbine. The newer high bypass engines route most of the air around the turbine, and are more fuel efficient, but slower. In fact, there are more efficient ways of doing other things, such as boarding planes, but they're not as profitable, so they'll never catch on – <http://digit.in/slwbdr>

High Bypass Engine

Low Bypass Engine

Airplane manufacturers save costs by making slower planes as they are smaller and lighter to build.

Airlines fly their planes at speeds where the engines are the most efficient, instead of the top speeds of the plane.
