Boston Dynamics Spot Mini

If you've been reading this section regularly then you've probably come across one or two of Boston Dynamics' robots. You'd also know who to blame when robots finally take over the world. Their newest robot is a redesign of their Spot Mini, which has now figured out how to open doors.

It does this with it's uh... face? Arm? We don't know. Claw attached to it. In a video teaser, we can see one Spot Mini with the attached claw opening the door with relative ease and quickness for it's pal Spot Mini

without the attached claw to waltz through. Probably to get its own face-claw.

The video is quite impressive and you can watch it here: <http://dgit.in/clevergurl>

Other than that though, the teaser doesn't give away much more about the new robot. We don't know if the robots were functioning autonomously here or if someone was controlling them from outside the frame. But if it was autonomous and the Spot Mini was actually able to help its friend through the door, maybe we should start worrying?

PocketSprite

The PocketSprite is a miniature gameboy, one small enough that it could fit on a keychain! The keychain Game Boy concept is not a new one though, and creator Jeroen Domburg had teased a DIY version of a Game Boy that could fit on a keychain about a year ago. The PocketSprite is a collaborative venture by him and Steve K.

The device packs quite a lotta hardware for its size. An OLED screen, Bluetooth and Wi-Fi support, a rechargeable battery, and a built-in speaker. It runs on a dual-core, 240MHz ESP32 chip and 520 KB of RAM. While that doesn't sound like much, it's actually more powerful than the original Game Boy which only had a 4.19 MHz processor and 16 KB of RAM.

The PocketSprite features built-in emulators which can emulate Game Boy, Game Boy Colour, Sega Master System and Game Gear games. As an added bonus, the device will also be open source, so if you've got the coding skills, you can load whatever you want onto it. Adding ROMs to the device is done using a local Wi-Fi network which device itself creates, allowing users to upload

eSight Smartglasses

You've probably seen a video or two online of a deaf person who is able to hear for the very first time thanks to cochlear implants. Or even of a colorblind person who's able to see colours for the first time. Well, here's a device that one-ups all that! The eSight smartglasses can give legally blind people the ability to see, and not just see, but in some cases, see better than 20/20 vision! To be clear though, this isn't for totally blind people, but for legally blind people who still have partial vision.

In terms of looks, the eSight looks like a visor, kind of like a lightweight VR headset. They've got corrective glasses built into them if needed. What it does is record the world with its high-speed cameras and project the image onto a pair of OLED screens. Then, special software is used to enhance and clean the image. All this happens in real-time, so there's

no lag. The visor can be lifted and lowered without ruining peripheral vision.

The glasses can be used to actually zoom into things, which is why you could end up with better than 20/20 vision. What's more, there's an HDMI port on it, which can be used to watch movies, making it as good as a VR display. The only downside? It costs \$10,000.
