

Apple LED displays

Reports suggest that Apple is working on developing its own displays at a secret manufacturing facility in Santa Clara, California <http://dgit.in/appledisplays>

Doodle in AR

Google's 'Just a line' app allows users to doodle in AR and create fun videos. <http://dgit.in/ARDoodle>

is electron. To install the package via npm you need to write the following command.

```
npm install electron --save
```

DEVELOPING THE FRONT END

The front end part of our application is associated with one html page. That is index.html. In that page we have created 2 forms for registration and login and one input field for taking input from the user. There is also another part for the chatting part of the user.

Now the first part of any Electron application is to create a browser window object. For that purpose you need to include the Electron library using **require**. After that we are going to de-structure the exported data into two main objects. One is **app** and another one is **browserwindow**. The code for that looks like this.

```
const {app, BrowserWindow} =
require('electron');
```

Now along with these two we are also going to require path and url for utility purpose. That can be done by **const path = require('path');** **const url = require('url');**

Now over here we are going to create a function that will define a browser-window where the index.html page will get rendered. (Code: <https://dgit.in/Dev1>)

Here the **createWindow** function creates a new **BrowserWindow** object **win**. That object then is associated with a url and that url is of the file that we have within **view**. We have also provided some options to the **BrowserWindow** object. **Height** and **Width** defines the initial height and width of the window and background color provides color.

To start our app we need to make some changes in the **package.json**. In **package.json** just add the following line in the scripts.

```
"start": "electron ."
```

Add the following code in the **index.html** page: <https://dgit.in/Dev2>.

And just start the application with **npm start** in the command prompt. The result of that will create a new window with the Html code that you have provided to it.

The output will now look somewhat like this.

Now go ahead and make some changes and just refresh the page like you would have done it with the normal browser window. Your changes will be reflected.

Now we are going to add two forms within the page. Now we will create two new forms, one for user to login to the application and another one for the user to register into the application.

So the First form looks like this

Along with that, the registration form looks like this.

So for the registration part we have to make a form submit where we are going to add the user details into the database. The fun part of Electron is you can have either html5 apis for your stuff or you can have some npm modules installed and can use them in the script. We have created a new js file to have all of our js codes for the page. Now the the dom is manipul-

*CODING MATTERS

OpenJDK

*JDK 10 has been released

The latest version of Java, JDK 10, has been released, just six months after Java 9 hit the shelves.
