

Telegram to be banned in Russia

Russia bans messaging application Telegram as it restricts authorities from reading its user's messages. <https://dgit.in/russiotelegram>

ZTE may lose Android License

ZTE's Android Software License loss may doom Axon 9, cannot use Qualcomm processors, Google apps. <https://dgit.in/zteandroid>

choice (we went with Notepad++). In this file, you'll find code that will look pretty familiar if you've worked with React before. Go to line 34 and change it as shown below:

```
// From
<h1>Profile: {user}</h1>
// To
<h1>Hola {user}!</h1>
```

Hit save and visit the original address at <http://0.0.0.0:8080> again (It should refresh on its own. If it doesn't, open the command tool where the application is running and let it rebuild). In there, click on 'John' to see the changes reflected.

The changes should be reflected

It's time to take our understanding of this framework one step further. Let us add a new Component to do that. For that, you need to create a new folder, Github inside routes. Once the folder is created, create an `index.js` file inside it. Our objective is to create a component that will fetch the number of followers of a given user from Github's API. The code can be found here: <https://dgit.in/gitcomp>.

To add some style elements, create `styles.css` in the same folder and add the following code in it.

```
.container {
  padding: 56px 20px;
  min-height: 100%;
  width: 100%;
  background: #EEE;}

```

As of now, the component is ready and needs to be imported. To do that, we need to connect it to routes and add it in the header for the main app for successful navigation. Go to the `src` folder in the root of your application's directory and edit the `index.js` file. You need to replace the code in the file with the following code: <https://dgit.in/CompPrec>.

Following that, go to `<your app>\src\components\header` and edit the `index.js` file to add the new `Link` tag as follows.

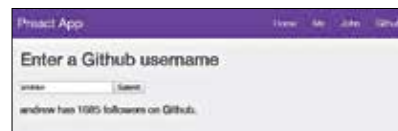

```
<Link activeClassName="active"
href="/github">Github</Link>
```

At this point, you may need to refresh your app to see the output but the page should eventually have a new 'Github' tab that should look like this.

It's almost ready

Feel free to try it out. Pick any random user name from Github and input it here. The output should look like this:

A sample output.

Congratulate yourself – you've just built your first functional component in Preact. Seems too easy right? But we're not done yet. There's one more step involved for this build to be complete.

SHIP IT

Now that everything is ready, it is time to deploy your application. But before we do that, there's a lesson to be learnt. Go to your browser's developer tools. Since we were on Chrome, for us that meant navigating to the triple-dot menu, scrolling down to **More tools** and clicking on **Developer tools** (the shortcut is **Ctrl+Shift+I**).

Navigate to the network tab and find `bundle.js` to note the size of the asset. You can see what our files looked like in the screenshot below. We got a file size of 181B. Note this down as it will be useful later.

Now, go to the root directory for your project (the one under System32),
