OVERCLOCK YOUR DEVICE

Every smartphone company installs a maximum CPU clock frequency in place to prevent phones from encountering unaccounted errors and stop CPU chips from being privy to overheating tendencies. However, with a rooted device, you can overclock your CPU, a few megahertz at a time, until it arrives at optimal performance. Root access allows users to install custom kernels that aid overclocking or downclocking (if you want to boost up your device's battery life). The custom kernel used for this process will be different depending on your phone which aligns with your device's processor and hardware configuration. Be mindful about a few things before overclocking, it drains battery life in accordance with how much you have boosted the CPU clock frequency and installing the wrong custom kernel for your phone can risk bricking the device. Once the custom kernel has been successfully installed, overclock your smartphone's CPU a few megahertz at a time, and test out what works best for you. If the phone becomes glitchy, revert to a lower frequency.
