PET is more durable than other material

you need to hold it in place. For that you can use rubber heat-shrink wrapping. Simply put them across the PET cable and let it end right before the metal pin. Take a heat gun or a lighter to the shrink-wrap and watch the magic happen. You've now prepared one wire out of the entire bunch. Rinse-repeat till all wires in the cable or bunch are sleeved. Once that's taken

Cable clips

care of, you'll need a clip to hold all your freshly sleeved cables neatly.

You can cable clips in plastic or metal. The safest choice, which we're veering towards, is plastic just so that we don't end up shorting anything inside our PC cabinet. That's it. You've now figured out how to sleeve your PSU cables. Let's move onto the next most important - and popular - aspect of PC modding. We're talking about liquid cooling.

CUSTOM LIQUID COOLING

You can easily buy an All-In-One closed loop liquid cooler and you'd be set but where's the fun in that? A custom liquid cooling setup is an expensive affair but it also pays off wonderfully because, like all things custom, you have the ability to change things

up and build a setup that's unique to your system. Here's how you can go about building one.

The first step in building a liquid cooling system is to figure out if your case can support it and by that we mean if it has space to put a radiator, reservoir, pump and all the relevant tubings. If not, you can always mod your cabinet to fit your cooling system.

There is certainly a risk in liquid cooling. Should a tubing crack and leak a few drops of coolant onto any of the exposed components in your system it'll go up in smoke. Which makes liquid cooling cumbersome in a way. You have to schedule regular maintenance sessions to clean the tubes and service the radiators to ensure there's no gunk build up. On the flip side, liquid cooling makes your PC really silent. Since liquid cooling is more efficient at cooling things down, the fans on a liquid cooler need not run at a high RPM. Unless of course, you've got a really dense radiator or the fan has high static-pressure.

Like all mods, liquid cooling has a functional aspect and also an aesthetic aspect. Which aspect becomes the highlight of your build comes down to how you put together the entire setup. Let's take a look at all the different components of a liquid cooling system. First you have the tubing which can be either flexible or hard tubing. The former is easy to configure, set up and maintain while the latter takes

a lot more effort to build. However, hard-tubing is way better looking than flexible tubing. As we said, your choice would depend on the priority you assign to the aesthetics and functionality respectively. There are different brands which provide tubing but the general consensus is to go with anything made by 3M. They're clearer and stay that way for far longer than

Liquid cooling setup

non-branded ones. For hard-tubing you can either go with transparent material made of acrylic/plexiglass/PETG tubing or you can go with an opaque material like copper or aluminium. They're all different to work with and which one you choose depends on the material. While getting tubes, it's important to keep an eye on the measurements. Tubing has two parameters, the inner diameter(ID) and the outer diameter(OD). When you're putting in the fittings, the tube measurements need to match the fitting for a tight fit, otherwise you're just asking for an accident to happen.
