How to setup a secure communication system using open source tools

For the people paranoid about third-parties or hackers snooping on your communication channels.

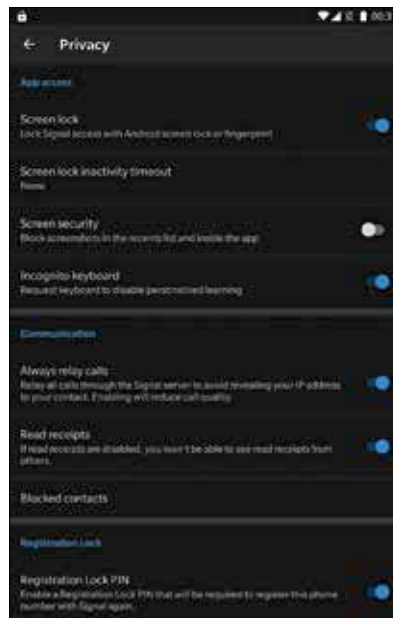

Abhijit Dey | abhijit@digit.in

Internet users may feel the need to be careful while communicating. You can't be sure whether someone is snooping in on those conversations or simply recording them at their end. It is also better to be safe when using public internet services since it's difficult to determine whether the connection has been compromised. If you belong to this category of cautious interweb users, this is how to get started on maintaining privacy and security while communicating.

INSTALL A SECURE MESSAGING APP

Texting is the easiest and quickest form of communication. There are hundreds of the instant messaging apps out there. Since most of them are directed towards regular users, they incorporate basic features for protection and privacy. End-to-end encryption is something that the big players have already introduced into their services. Some have also included password protection and two-factor

authentication but that's about it. Open Whisper Systems has a dedicated application where you can benefit from better security and privacy features. Apart from the end-to-end encryption and password protection, you can disable screenshots inside the app, relay your calls through their servers for complete anonymity and register your number with a unique PIN. Relaying calls will mask your IP address to the caller, so you can't be tracked. This is done by relaying the calls through

Lock Signal using a numerical passcode or your fingerprint

Signal's server at the cost of lower call quality. By registering a lock PIN for your number, every time you log into the application, say, on a new device, then only you can access your account with the unique PIN. Of course, all

these features will only work when both the sides are using Signal. You can create groups with other users as well and continue using the same features. Signal also supports one-to-one video calls but not group video calls. Edward Snowden has himself endorsed Signal. Signal is available on Android, iOS and Windows Desktop.

SEND FILES OVER AN ENCRYPTED CHANNEL

During conversations, you might feel the need to share documents or pictures or even videos. Firefox is working on an experimental feature called Firefox Send to send files securely to someone, hosted for a limited time. Although storing files for a limited time isn't new, the feature allows you to restrict the number of downloads as well. So, if you intend on sharing the file with only one person, then you can set the number of downloads to just one. It's a web-only tool where you upload your file from the web browser. Once uploaded, it generates a public URL that can be shared. To ensure security, you can attach a password to the file as well. The one using the link will need to enter the password to be able to download the file. Currently, the feature holds the file you shared for 24 hours and we believe in the future they might allow you to change the duration. If you've already sent something from your browser, it will remember the files and list them down with the number of downloads, time since it was uploaded and the shareable URL. The file size is limited to
