1GB covering all types of files. Firefox Send doesn't ask you to create a profile or log into any service. Just visit the website, upload your file and share the link. Even though it's an experimental feature, it's pretty solid to use it on a daily basis without worrying about someone else going through your files. Since this is a web tool, the service isn't restricted to Firefox users.

CREATE AN ENCRYPTED EMAIL ACCOUNT

Without some basic levels of security, you won't even know if you've been hacked and someone else is also using your email account. Gmail does notify you about new logins from different browsers and even locations, and it also incorporates two-factor authentication. However, Gmail still hasn't implemented end-to-end encryption natively. There's also the fact that Google reads or scans your emails. That's how your flight and movie reservations are automatically added to your Google Calendar. If this already scares you, then you should switch to Protonmail. Things are a little different here where they have implemented end-to-end encryption in their email service. It only works when the emails

are sent between Protonmail users. The company goes on making a bold claim that even they can't read your emails since every email kept on their servers are encrypted and they don't possess the encryption keys of their users. This means even if someone hacks into their servers, no one is getting access to your email content. If you intend to share sensitive information with someone using a different email service, you can encrypt your email with a password. The encrypted email will appear as a normal email in the inbox of the recipient with an embedded link. The link takes you to another webpage where you enter the password and the subject body is finally revealed. You can also assign self-destruct timers to emails and add passwords to them. This is applicable to both users of the service and outside. Protonmail offers all the security services available in Gmail except the ability to generate physical security keys. Going the extra mile, this service allows you to generate and download your PGP keys directly from your account rather than relying on setting it up manually. The free version of Protonmail offers you a storage of 500MB, limit of 150 messages daily, and the capability to create up to three folders

or labels. If you see yourself regularly using the service and wanting more features, you can opt for the paid subscription. Protonmail is available on Android and iOS as well.

VIDEO CHAT WITH MULTIPLE PEOPLE SECURELY

Once you get into the habit of securely communicating with people, you might want to take up video calls as the next step. Jitsi Meet is an easy to use tool and it runs right from your web browser. They do have a software called Jitsi but it's used for old messenger accounts such as AOL or Google Talk. Rather than going through the hassle of logging in and using the software, Jitsi Meet doesn't require anything. On their landing page, all you need to do is enter a nickname or use the auto-generated ones and hit "Go". The nickname entered on this screen will also be appended to the URL, forming a custom URL that can be shared to invite people. On the bottom right, you can find details for inviting people. There are several dial-in numbers present for different countries. You can also add a password to these invitations. The tool is targeted for video conferencing where you can chat, share your screen (after installing their browser extension) or write on a shared document collaboratively (buggy for now), etc. It includes an option to share YouTube videos which can be controlled by the user who shared it. The YouTube video is inserted into the UI as a regular user whose view can be switched and paused. Another interesting feature is to go live on YouTube straight from the tool. The feature is currently in beta testing. With the option of not having to create or log in with an account and having encryption implemented, your activity isn't being stored anywhere. Snowden was also seen using Jitsi Meet at one conference. Jitsi Meet has apps on both Android and iOS, so you can use the custom URLs to join video calls from your mobile devices.
