Surprising AI

This paper is a collection of anecdotes, where artificial intelligences managed to surprise their creators. <https://digit.in/sep18-17-2>

Absurd Input Devices

In the pursuit of ergonomics, accessibility, innovation or necessity, there have been input devices produced that look like they have escaped from a science fiction movie.

DATAHAND PROFESSIONAL II

This is a really futuristic keyboard where your fingers sit permanently in key wells. Moving them in the four cardinal directions allows you to feed in different keys. The keyboards were designed for data entry professionals, and since your fingers were moving in directions other than up and down, it reduced the chances of repeated stress injuries. The mouse is integrated, and the keyboard was actually seen in *Contact*.

MASSAGE ME

The idea of this input device is to provide commands for a videogame through a massage. It allows you to play a game while spending quality time as well. This is an input device that requires you to actually hack a controller. The Massage Me is not a product available on the market, you have to build it yourself. If you are interested, then check out the instructions here: <https://digit.in/msgme>

SPACEMOUSE COMPACT

The Spacemouse Compact by 3DConnexion solves an important problem for 3D artists. The standard mouse is very clumsy when it comes to using 3D applications, and manipulating virtual objects. The mouse offers six degrees of freedom, and allows you to scale and transform 3D objects with less effort, and more precision than is possible with a standard mouse. The mouse can be used in tandem with a standard mouse.

OCZ NEURAL IMPULSE ACTUATOR

Team Digit actually got to try this device way back in 2009. The device promised to translate commands from your brain into inputs for gaming. What you could really do with it was to train it to understand facial contortions and grimaces as particular inputs. Then you had to make the same faces again while playing. It sort of worked, but was practical only if you were Mr Bean or Jim Carrey.

ORBITOUCH KEYLESS KEYBOARD

This is a “keyboard” without any actual keys in it. The keyboard consists of two domes that can be rotated into a combination of positions. The right dome has a colour key, and the left dome has a set of keys assigned to each of those colours. When the two domes enter into a new position, the key gets typed. This keyboard has been designed for people with disabilities, injuries or impairments. [1](#)
