

Lolcode

The programming language equivalent of lolspeak. KThxBye.

Arunava Roy Choudhury |
 feedback@digit.in

If, after all the years you've spent on the internet, you weren't convinced that lolspeak is the greatest thing to happen to the internet since Rickrolling, you would be happy to know that one Adam Lindsay, researcher at the Computing Department of Lancaster University, created a programming language on it. Here's how it works.

SETTING IT UP

Installation on Mac:

- Press Command+Space, and type Terminal and press enter/return key
- Run in Terminal app

```
$ git clone https://github.com/justinmeza/lci.git
$ cd lci
$ cmake.
$ make && make install
```

Installation on Windows:

- First add MinGW and Python to your environment variables path. To do this, right click on My Computer, choose Properties, then select Advanced system settings. Select Environment Variables. In this box, select the PATH variable and then click Edit.
- Now, add ;C:\MinGW\bin;C:\Python32 to the end of that path.
- Next, open the Command Prompt and navigate to the project directory using the **cd** command, for example.
- Run the script **install.py**.

SYNTAX

Comma

The comma in lolcode behaves like the equivalent of a newline in most languages, for example, \n in Java and C. You can write many commands in a single line in LOLCODE, provided that you separate them using a comma (,).

Three Periods (...)

The three periods is the opposite of the comma, it enables you to combine multiple lines of code into a single line or a single command by including (...) at the end of the line. This makes the compiler treat the content of the next line as the content of previous line. Infinite lines of code can be written together as a single command, as long as each line is ended with three periods.

A comment is terminated by a new-line. Please note that the line continuation (...) and (,) after the comment (**BTW**) are ignored by the lci.

Too Long Didn't Read

Single line comments are written followed by the **BTW** keyword. They may occur anywhere inside a program body: it can be at the first line of program, in between the program, in some line, or at the end of a program. All of these are valid single line comments-

```
I HAS A VAL ITZ 19 BTW VAL =19
I HAS A VAL ITZ 19,BTW VAL =19
I HAS A VAL ITZ 14
BTW VAR =14
```

In LOLCODE, multiple line comments are written followed by **OBTW** and they are ended with **TLDZ**.

This is a valid multi-line comment -

```
I HAS A VAL ITZ 51
```

KEYWORD	DESCRIPTION
BTW	This begins a single comment line
HAI	This represents the entry point to a program and can be treated as the equivalent of main() function
I HAS A <type> <variable>	This represents the declaration of a variable of a specific type. Possible types are: ▪ NUMBAH (int) ▪ DECINUMBAH (double) ▪ WORDZ (std::string)
GIMMEH <variable>	This asks for an input from user and assigns it to the required variable
GTFO	This is the equivalent of break statement, usually used to break out of loops
IM IN YR LOOP	This initiates an infinite loop and can be treated as the equivalent of while(true) for other languages. It can only be exit using GTFO command
IZ <expr1> <operator> <expr2>?:	This represents an if block where the operator can be one of BIGGER THAN, SMALLER THAN, SAEM AS.
