

## Controllers for the disabled

Microsoft has taken in the inputs of disabled gamers to design new accessible controllers for the Xbox. <https://dgit.in/sep18-51-1>

## More memory

Scientists have developed the world's densest SSD, promising to improve storage by 1,000 times. <https://dgit.in/sep18-51-2>

```
if expression is satisfied>
    OMGWTF
    <code block to execute
as a default case>
OIC
```

## LOOPS

Loops are used in programming to execute a set of statements multiple times. They both simplify code and reduce redundancy. Simple loops are represented with IM IN YR <label> and IM OUTTA YR <label>. Loops defined in this way are infinite loops and they should be terminated with a GTFO break statement.

```
IM IN YR <label> <any_op-
eration> YR <any_variable>
[TIL|WILE <expression>]
    <code block to execute inside
the loop multiple times>
IM OUTTA YR <label>
```

Please note that inside the loop, UP-PIN is used to increment by one and NERFIN is used to decrement by one. The TIL keyword is used to calculate an expression as a TROOF. If it evaluates as FAIL, the loop continues once more, if it evaluates as WIN, then the loop stops, and continues after the next IM OUTTA YR statement.

The WILE keyword is equivalent of while in other languages and the opposite of TIL keyword, if the expression is WIN, execution continues, otherwise the loop exits.

### HAI 1.2

```
I HAS A VAR ITZ 0
IM IN YR LOOPY UPPIN YR VAR
TIL BOTH SAEM VAR AN 10
    VISIBLE SUM OF VAR AN 1
IM OUTTA YR LOOPY
KTHXBYE
```

This program will output the numbers 1 to 10.

## FUNCTIONS

A function carries the same parlance as in other languages, a set of instructions that can be named and invoked as required. In LOLCODE, a function's definition starts with the keyword "HOW IZ I" and the closing keyword is "IF U SAY SO".

```
HOW IZ I <function name> [YR
```

```
<parameter/argument> [AN YR
<other_arguments...> ...]]
    <code block to execute /
Set of statements to execute>
IF U SAY SO
```

In LOLCODE, a function can accept only a certain number of arguments as an input. The arguments or parameters, are the identifiers that become a variable to the function. Functions can't access any values other than those passed to them as arguments.

## RETURNING VALUE FROM A FUNCTION

In programming, a function can return some value to the program when its execution is completed. In LOLCODE FOUND YR <any\_expression> returns the value of the expression when function block is executed completely. If no other return statement is found, then IF U SAY SO is executed and the value in the IT variable is returned.

## CALLING FUNCTIONS

While calling a function, the syntax is the function name, followed by the number of arguments that the function will accept. These arguments can be simple variables or any expressions. If a function accepts any expression instead of a simple value, then the expressions' values are calculated before the function is called. Please note that the number of arguments a function will accept, should be defined in the definition of the function.

### HAI 1.2

```
HOW DUZ I LUNCH
    I HAS A FOODZ
    GIMMEH FOODZ
    FOUND YR FOODZ
IF U SAY SO
    VISIBLE LUNCH
KTHXBYE
```

Output

```
$ lci main.lol
Pizza
```

Congratulations, now you've learnt all the basics you need to know to build your own code in what is perhaps the pinnacle of human computing technology. If you're interested to build a simple calculator using lolcode, you can find the code here: <https://dgit.in/Lolcal>. 🇮🇳

## \*CODING MATTERS

## \*OpenAI Five Defeated But Undaunted

OpenAI's team of Dota 2-playing bots lost both the games it played at Valve's International Dota 2 tournament in August.

<https://dgit.in/OpenAIDotaLoss>

## \*Amazon Releases Cameras Recap API

There's a new API from Amazon that can be used to let apps play video feeds recorded by smart home cameras. The Cameras Recap API can be used to view videos on Echo Show, Echo Spot, Fire TV, and Fire Tablets.
